First we create a piece of code that contains nothing but an empty module and some skeleton code, as follows: First sketch. In the case of the Finnish example above there will be many more pointers and primitive elements, as you can imagine. Let's make sure we understand why the system must work in this way. When a new word is introduced into a language, say a verb such as to google that came into existence in the 1990s, all English speakers will automatically assume that it has the past form he google+d and third person form he google+s. From a syntactic perspective, case is an epiphenomenon, relating to several separate nominal categories. In the morphology, case becomes identifiable as differing from adpositions in many languages, cases. Chapter 1. case in morphology and syntax. 7. Inherent Cases, on the other hand, are interpretable features, and are assumed to be found in positions where a  $\bar{1}$ -role is also assigned by the predicate. Firstly I provide further examples of the overlap between the two categories in a cross-linguistic perspective, and describes work taking this overlap into account, most notably Fillmore (1968), who argues that cases spell out the category P, and Grimshaw (2000), who argues that P is in the extended projection of the noun.
